

Lab Assignment 4

Steven Truong

Task 1

Assume that at a given step n , we have $\boldsymbol{\mu}^n$ and r^n .

In the first phase of minimizing $E(\boldsymbol{\mu}^n, r^n)$, for each \mathbf{x}_i in our data set, we assign

$$r_{ik}^{n+1} = \begin{cases} 1 & \text{if } k = \arg \min_{1 \leq j \leq k} \|\mathbf{x}_i - \boldsymbol{\mu}_j\| \\ 0 & \text{otherwise.} \end{cases}$$

This clearly causes E to decrease (or stay the same) because we replace the previous $\|\mathbf{x}_i - \boldsymbol{\mu}_j\|$ term with the one that gives the minimum norm.

In the second phase, we have $E(\boldsymbol{\mu}^n, r^{n+1})$, and minimize with respect to $\boldsymbol{\mu}^n$. Since E is convex as a function of $\boldsymbol{\mu}^n$, then $\boldsymbol{\mu}^{n+1}$, which gives a 0 gradient, must be the global minimizer with our given r^{n+1} . Hence, in this phase, E must decrease (or stay the same) also.

Thus, the k -cluster means algorithm guarantees descent at each step.

Task 2

In one step of the algorithm, we have to calculate all the norms between \mathbf{x}_n and $\boldsymbol{\mu}_j$ in order to update r .

We first have to calculate the centroids, which are given by

$$\boldsymbol{\mu}_j = \frac{\sum_{n=1}^N r_{nj} \mathbf{x}_n}{\sum_{n=1}^N r_{nj}}.$$

So, for the k classes, we have to do N products, $2N$ sums, and a division, which gives us an upper bound of $k(3N + 1)$ steps for the calculation of the means.

We then have to calculate all the norms $\|\mathbf{x}_n - \boldsymbol{\mu}_j\|$, which involves d subtractions, multiplications, and sums for Nk pairs of \mathbf{x}_n and $\boldsymbol{\mu}_j$, which gives us $3Ndk$ calculations to figure out how to update r_{nj} .

So, each update has $k(3N + 1) + 3Ndk$ calculations total.

Task 3

Because of symmetry, if we had $\boldsymbol{\mu}$ which gave us a minimum, we can switch around the order of the $\boldsymbol{\mu}_j$ and have the same minimum, but with class labels changed. Convex functions must only have one minimum, so if k is at least 2, then $J(\boldsymbol{\mu})$ is not convex.

Task 4

```

1 load iris_data.mat
2
3 [N, d] = size(data);
4 global k;
5 k = 3; % Number of classes
6
7 %%% Helper Functions
8
9 % Given r and j, this computes |Cj|
10 function y = clusterSize(r, j)
11     y = sum(r(:, j) == 1);
12 end
13
14 % E step (calculating means)
15 function newMu = updateMu(data, r)
16     global k;
17     [N, d] = size(data);
18
19     newMu = zeros(1, d);
20     for i = 1:k
21         currentSum = zeros(1, d);
22         for j = 1:N
23             if (r(j, i) == 1)
24                 currentSum = currentSum + data(j, :);
25             end
26         end
27         cSize = clusterSize(r, i);
28         newMu(i, :) = currentSum / (cSize + (cSize == 0) * eps); % Avoid division by 0
29     end
30 end
31
32 % M step (updating r)
33 function newR = updateR(data, mu, r)
34     global k;
35     [N, d] = size(data);
36
37     newR = r;
38     % min always takes the first occurrence of the minimum,
39     % so we don't have to worry about infinite loops
40     for i = 1:N
41         norms = zeros(k, 1);
42         for j = 1:k
43             norms(j) = norm(data(i, :) - mu(j, :));
44         end
45         [M, I] = min(norms);
46         newR(i, :) = zeros(1, k);
47         newR(i, I) = 1;
48     end
49 end
50
51 % Assign via random partition method (RPM)
52 function [mu, r] = rpm(data)
53     global k;
54     [N, d] = size(data);
55
56     r = zeros(N, k); % The row is the data point, and the columns give its current classification
57     for i = 1:N
58         col = ceil(rand * k);
59         r(i, col) = 1;
60     end
61     mu = updateMu(data, r); % updateMu just calculates the means, essentially
62 end
63
64 % Assign via the Forgy method
65 function [mu, r] = forgy(data)
66     global k;
67     [N, d] = size(data);
68
69     r = zeros(N, k); % The row is the data point, and the columns give its current classification
70     p = randperm(N, k);
71     for i = 1:k
72         mu(i, :) = data(p(i), :);
73     end
74 end
75
76 %%% Main Script
77
78 % Initialization
79 [mu, r] = forgy(data);

```

```

80 while true
81     newR = updateR(data, mu, r); % E step
82     mu = updateMu(data, newR); % M step
83     if (r == newR) % Check if points were moved to a new cluster
84         break;
85     else
86         r = newR;
87     end
88 end
89
90 classifications = zeros(N, 1);
91 for i = 1:N
92     for j = 1:k
93         if (r(i, j) == 1)
94             classifications(i) = j;
95         end
96     end
97 end
98
99 mu
100 classifications

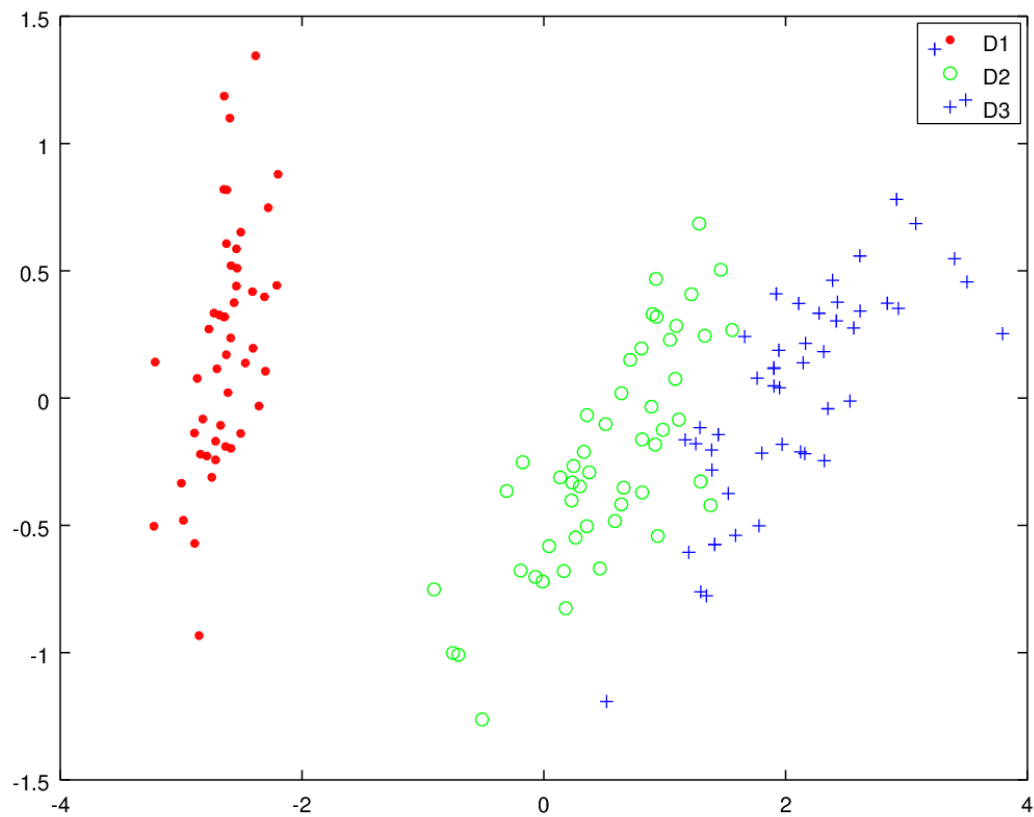

```

Task 5

On average, the Forgy method performed slightly better. Each cluster's purity for the Forgy method was larger every purity for the random partition method.

Forgy Method	Purity(C_1)	Purity(C_2)	Purity(C_1)
	0.88	0.88	0.87
Random Parition Method	Purity(C_1)	Purity(C_2)	Purity(C_1)
	0.85	0.82	0.80

Task 6

The performance of k -means clustering was fairly good because the classes roughly made up different clusters. However, class 2 and class 3 mixed quite a bit, so it was more difficult to separate those two classes when clustering the data points. So, 80–90% accuracy between the two methods on average is not surprising.
